The paper presents some techniques for extracting pitch and spectral envelope of a signal using sinusoidal model with instantaneous parameters.

The main features of the proposed algorithms are:

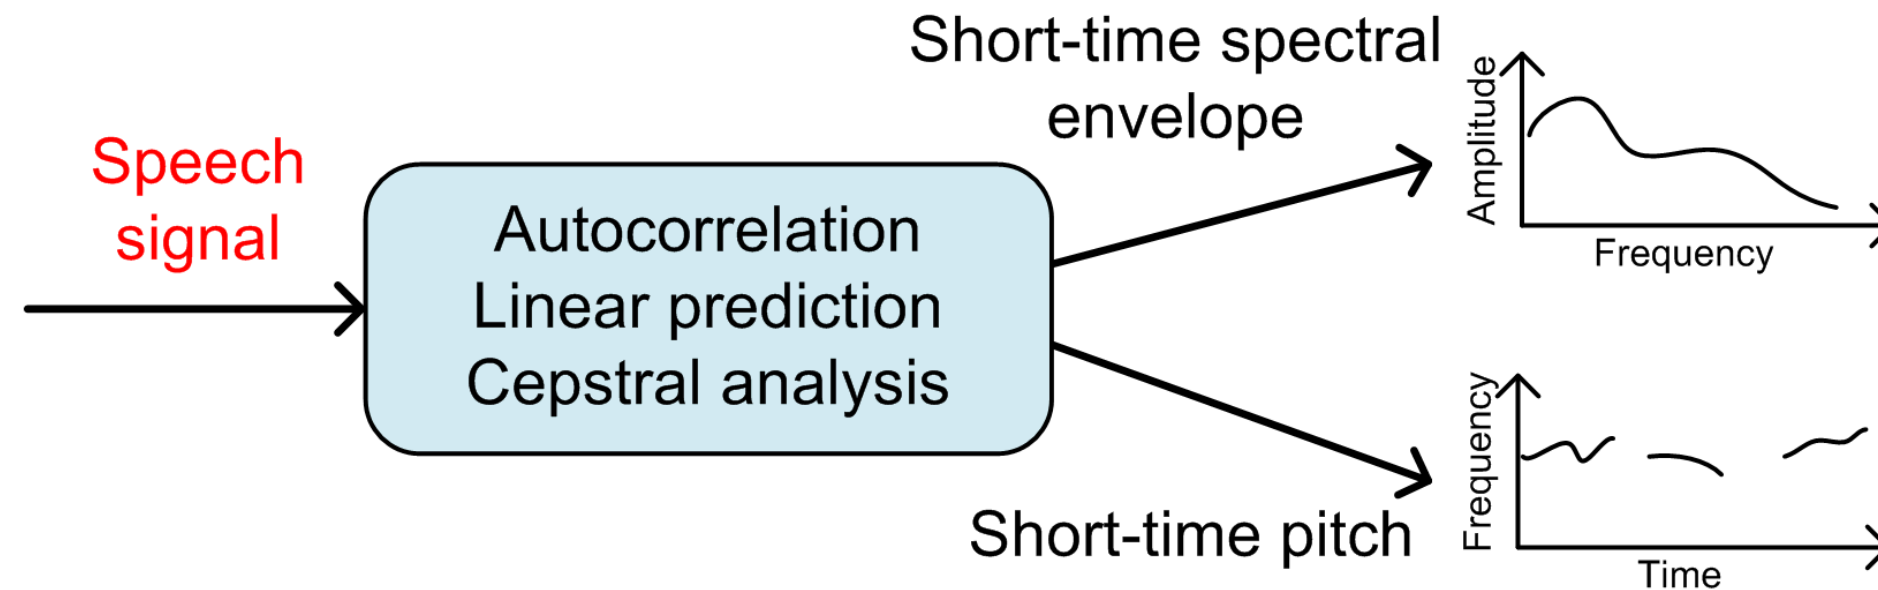

- model-based analysis that provides high time-frequency resolution;
- model-based estimation of instantaneous pitch
- model-based estimation of instantaneous spectral envelope;
- accurate envelope representation by linear predictors of high order.

Two-step analysis:

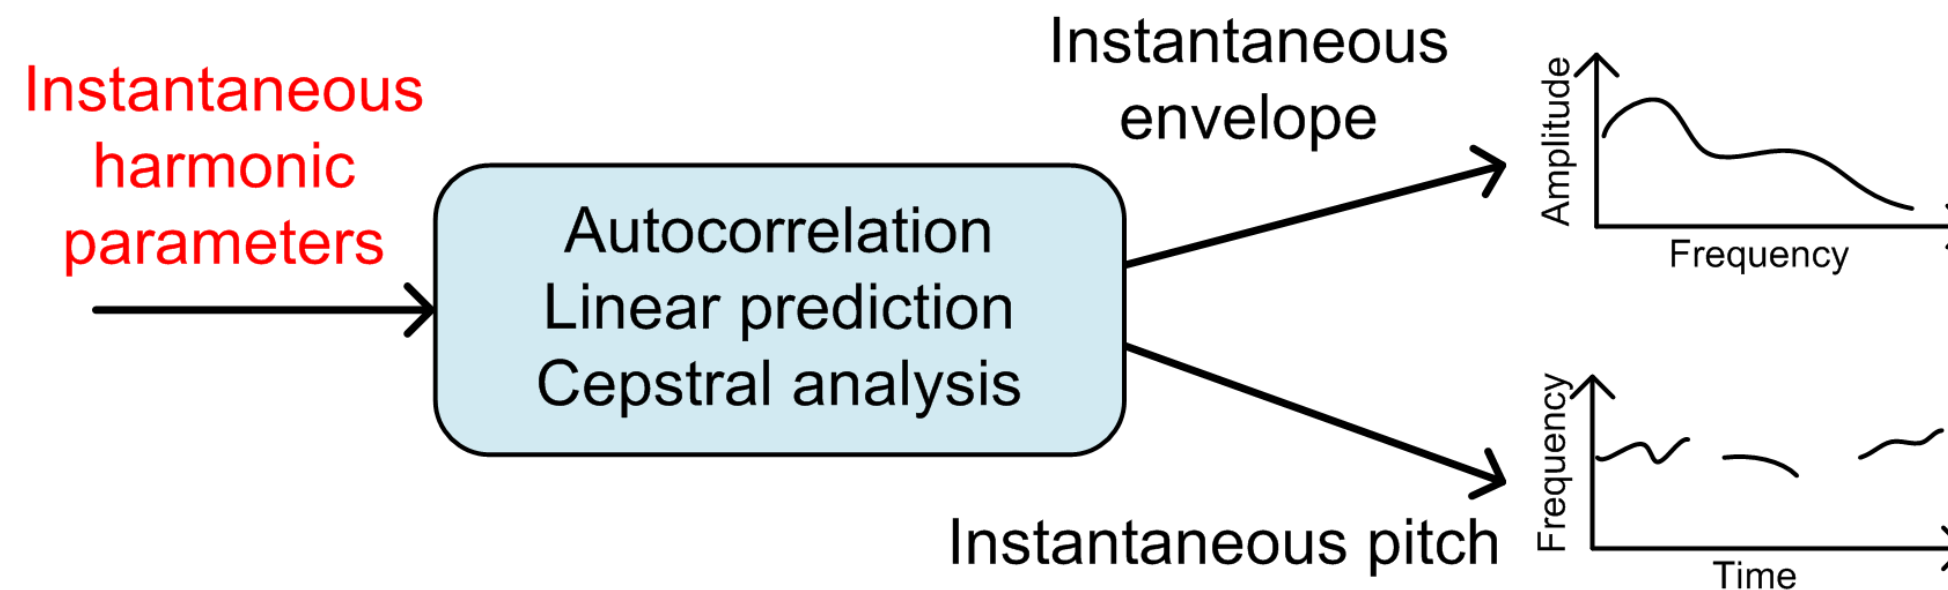

1. extraction of sinusoidal parameters;
2. parameters transformation to required characteristics

## 2. Model-based extraction of speech characteristics

### Classical extraction techniques

### Model-based extraction techniques

### 3. Estimation of instantaneous harmonic parameters

The signal  $s(m)$  is decomposed into overlapping bandlimited analytical signals  $S_{F_\Delta, F_c^i}(m)$ :

$$S_{F_\Delta, F_c^i}(m) = \sum_{n=-\infty}^{\infty} \frac{\sin(F_\Delta n)}{n\pi} w(n) s(m-n) e^{-jF_c^i n} = A_{F_\Delta, F_c^i}(m) \cos\left(\varphi_{F_\Delta, F_c^i}(m)\right),$$

where  $2F_\Delta$  - bandwidth and  $F_c^i$  - center frequency of the  $i$ -th band and  $w(n)$  - an even window function. Then instantaneous parameters are evaluated as

instantaneous amplitude

$$\longrightarrow A_{F_\Delta, F_c^i}(m) = \sqrt{R^2(m) + I^2(m)},$$

instantaneous phase

$$\longrightarrow \varphi_{F_\Delta, F_c^i}(m) = \arctan\left(\frac{-I(m)}{R(m)}\right),$$

instantaneous frequency

$$\longrightarrow F_{F_\Delta, F_c^i}(m) = \varphi'_{F_\Delta, F_c^i}(m),$$

where  $R(m)$  and  $I(m)$  are real and imaginary parts of  $S_{F_\Delta, F_c^i}(m)$  respectively.

# 4. Normalized cross-correlation function (NCCF)

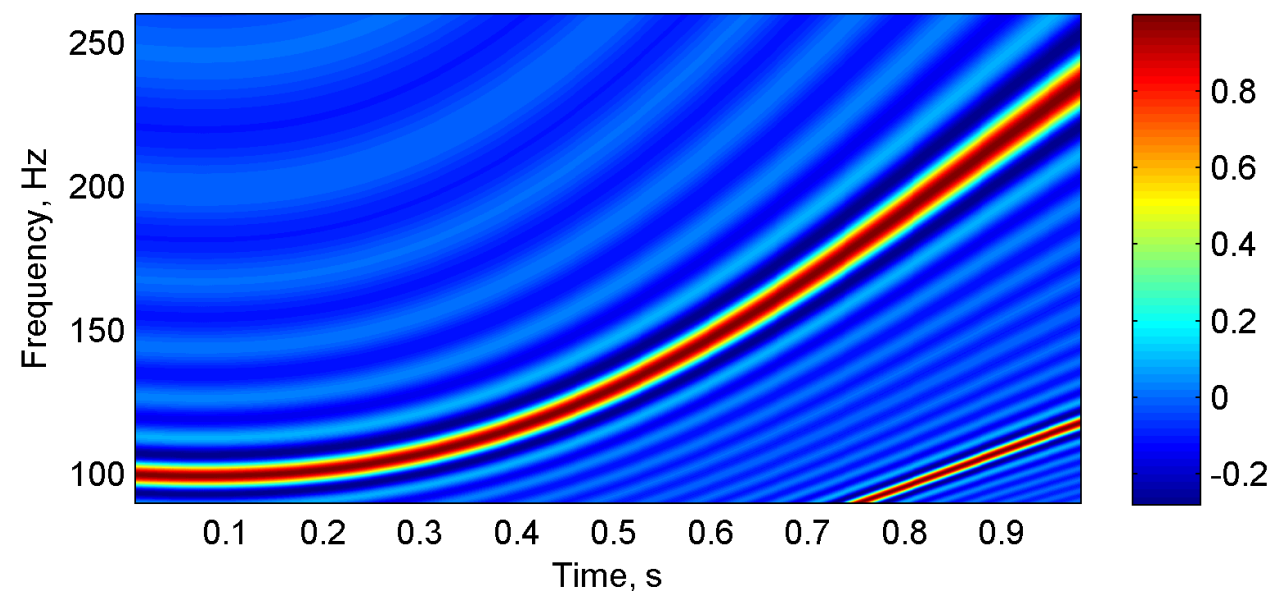

Time domain

$$\phi(m, k) = \frac{\sum_{i=m}^{m+n-1} s(i)s(i+k)}{\sqrt{e_m e_{m+k}}},$$

where  $e_i = \sum_{l=i}^{i+n-1} s_l^2$  and  $n$  – window size

Model-based estimation

$$\phi_{inst}(m, k) = \frac{\sum_{p=1}^P A_p^2(m) \cos(F_p(m)k)}{\sum_{p=1}^P A_p^2(m)}$$

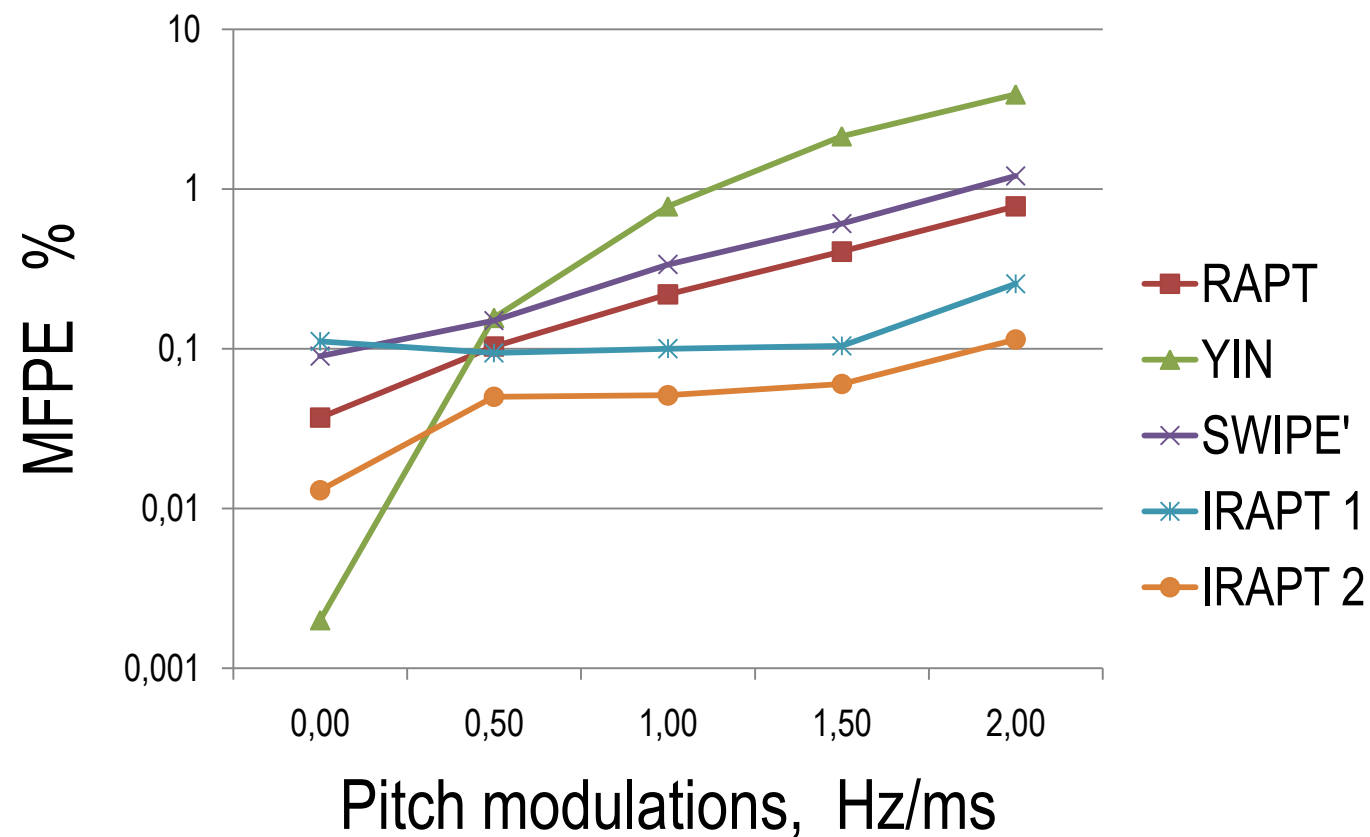

$P$  – number of bandlimited analytical signals

# 5. Experimental results of pitch extraction

The proposed technique is compared with other pitch estimation algorithms in terms of gross pitch error (GPE, %) and mean fine pitch error (MFPE, %).

Artificial signals

Natural speech

	Male		Female	
	GPE	MFPE	GPE	MFPE
RAPT	3.69	1.74	6.07	1.18
YIN <sup>3</sup>	3.18	<b>1.39</b>	3.96	0.84
SWIPE' <sup>4</sup>	<b>0.78</b>	1.51	4.27	<b>0.80</b>
IRAPT 1	1.63	1.61	<b>3.78</b>	0.98
IRAPT 2	1.57	1.57	<b>3.78</b>	1.05

## 6. High-order linear prediction

The coefficients are evaluated using the following system:

$$Q = \begin{bmatrix} q(0) & \cdots & q(p-1) \\ \vdots & \ddots & \vdots \\ q(p-1) & \cdots & q(0) \end{bmatrix} \begin{bmatrix} a_1 \\ \vdots \\ a_p \end{bmatrix} = - \begin{bmatrix} q(1) \\ \vdots \\ q(p) \end{bmatrix} \quad q(l) = \sum_{i=1}^{K-1} D(l, i)$$

where  $a_1, \dots, a_p$  – prediction coefficients,  $p$  – prediction order.

Each segment of the spectral envelope  $f_i \leq \omega \leq f_{i+1}$ ,  $1 \leq i \leq K-1$  is defined by a linear equation  $A(\omega) = b_i \omega + c_i$

$$D(l, i) = \begin{cases} \frac{b_i}{l^2} [\cos(f_{i+1}l) + f_{i+1}l \sin(f_{i+1}l)] + \frac{c_i}{l} \sin(f_{i+1}l) - \\ - \frac{b_i}{l^2} [\cos(f_i l) + f_i l \sin(f_i l)] - \frac{c_i}{l} \sin(f_i l) & l \neq 0 \\ \frac{1}{2} b_i f_{i+1}^2 + c_i f_{i+1} - \frac{1}{2} b_i f_i^2 - c_i f_i & l = 0 \end{cases}$$

# 7. Model-based linear prediction of speech

Source signal

Fourier spectrum

Autocorrelation,  $p=30$

Harmonic prediction,  $p=30$
